Current Data Usage Recommendation

After extensive examination of historic Chesapeake Bay Program (CBP) mesozooplankton monitoring data, and in consideration of the known methodological and data quality issues, the Chesapeake Bay Program is issuing the following data usage recommendation. Only mesozooplankton samples enumerated with Hensen-Stempel methodologies are recommended for use in quantitative analyses. These data have method codes MZ101A, MZ101B, MZ101C, and MZ103. Data quality issues have been identified for portions of the Virginia record. Virginia samples collected prior to 1993 and enumerated with method MZ102, and Virginia samples collected between 1993 and 2000 and enumerated with method MZ102 or MZ102B, should only be used for qualitative purposes. Species-specific correction factors have been developed for samples collected between 1993 and 1997 and enumerated with MZ102. Data adjusted by these factors have method code MZ102_C and can be used with discretion in quantitative analysis.

Background

The Chesapeake Bay Water Quality Monitoring Program included a zooplankton monitoring component from 1984-2002. Mesozooplankton samples were collected and enumerated by Versar, Inc. for Maryland and by Old Dominion University (ODU) for Virginia. Samples were collected with a towed, 202 μ mesh plankton nets at up to 36 fixed monitoring stations in the mainstem and tidal tributaries of the bay. Split sample comparisons in the later years demonstrated that numerous differences in field collection and laboratory enumeration procedures were significantly affecting data quality and comparability. These differences between and within laboratory methods have compromised the ability to combine data sets on a bay wide bases for development of zooplankton community health indicators, reporting of bay wide status and trends and support food web modeling efforts.

In the Maryland program, mesozooplankton were collected in the field, with stepped oblique bongo net tows at each station. Bongo nets were deployed 0.5 meters above the bottom and nets were raised in 1-4 meter increments (usually 0.5 to 1 .5 minutes/step) depending on station depth with a minimum of 5 steps per station. In the laboratory, samples were enumerated using a standard sub-sampling technique with a Hensen-Stempel pipette (HS) (Harris et.al. 2000). The technique was modified slightly three times over the 18 year history of the program. The standard Hensen-Stempel (HS) count and a whole sample scan for macrozooplankton was performed on each sample between 1984 and 1989 (denoted as method MZ101A). The macrozooplankton sample scan was temporarily discontinued from 1990 to 1996 (MZ101B). In 1996 the macro-zooplankton scan was reinstated and large bodied mesozooplankton species occurring in small numbers in the initial count were enumerated in special 850-micron sieve counts were also reported (MZ101C).

In the Virginia program, field samples were collected by taking five minute double-oblique pattern bongo net tows from bottom to surface. From 1985 to 1992, it is unclear whether or not the bongo nets used for field sampling were equipped with flow meters to accurately estimate the volume of water filtered through the nets during a tow. The volume of water filtered during a tow may have been estimated using the length of the tow and area of the net's opening. In 1993, a flow meter was mounted on the nets. In the laboratory, the Virginia program used several different enumeration techniques. From 1985 to 1997 a Controlled Variability Sampling (CVS) method (method MZ102) described by Alden et.al. 1982 was used. The CVS technique used a series of five wet sieves (200, 300, 600, 850, and 2000 microns) to separate and count zooplankton by size fraction. Split sampling tests in early 1998 revealed that smaller zooplankton slipped through the last 200 micron sieve and CVS enumerated samples consistently reported lower plankton densities than the HS enumerated samples (ICPRB, 2000). Furthermore, the sieving process appeared to break off fragile plankton appendages making taxa identifications more difficult. In March 1998 a 75 micron sieve was added to the sieve stack in hopes of capturing the smaller plankton lost by the original CVS method (method MZ102B). This modification to the CVS method was found to be ineffective (ICPRB 2000) and abandoned in favor of the Hensen-Stempel pipette method in 2000 (method MZ103).

Fortunately, as standard practice in the Virginia program, all original field samples were split into halves, one was enumerated and the other was archived. This presented an opportunity to recount archive samples using Hensen-Stempel methodology. Counts from archive samples could potentially fill data gaps in the historic record created by CVS enumerated samples and allow for the development of correction factors to make CVS data comparable with HS enumerated data, thus expanding the historic data record. In 2002, Old Dominion University went into the archives and counted 189 archive samples (Carpenter et. al. 2003). These samples served as the basis to develop correction factors for summer mesohaline and polyhaline CVS enumerated samples (Carpenter et. al 2006). No correction factors have been developed for samples enumerated with method MZ102B.

When all zooplankton sampling terminated in October 2002, approximately 1,000 split samples dating from 1996 to 2002 were in storage at Old Dominion University. In 2005, the CBP took formal custody of these samples with the intent to enumerate them with the pipette sub-sampling technique. Funding for recounting a portion of the archive samples became available from CBP in early 2006. Seventy-two archived Virginia mesozooplankton samples were counted by Versar, Inc. Samples collected during the summer (July- September) in mesohaline and polyhaline waters were targeted for counting because they could be used to validation samples for the Zooplankton Indexes of Biotic Integrity (ZIBI) which were in various stages of development. These samples also allowed for additional method comparisons, namely comparisons of HS method counts performed by the Maryland and Virginia laboratories, and comparisons of HS and CVS counts to further refine correction factors for method MZ102 counts originally published in Carpenter et al. 2006. The remainder of this report will address the

validation of the proposed zooplankton IBI's, various method/ laboratory comparisons and refinement of CVS correction factors.

Methods Comparisons

A major benefit of having the archived Virginia mesozooplankton samples enumerated with the Hensen-Stempel technique was that it allowed for two methods comparisons to be made. First, it allowed for a statistical comparison of Versar vs. ODU enumerated samples under identical enumeration techniques to better assess data comparability of the data between laboratories. Second, it allowed for the evaluation of the performance of correction factors developed for MZ102 (1993 – 1997 data). For both of these analysis data was first graphically assessed using log-log plots (Appendix A) to detect any obvious trends or biases over a variety of commonly calculated zooplankton metrics (Table 1). Note that the units for all data are in number of organism per meter cubed. The dot color denotes the methods of enumeration being compared. CVS corrected data is denoted as method MZ102_C. Three basic comparisons are shown: comparisons of Versar HS counts vs. corrected ODU CVS counts, ODU HS counts vs. corrected ODU CVS counts and Versar HS counts vs. ODU HS counts. Note that in the comparisons of Versar HS data against ODU HS data, the Versar counts are on the y-axis. The red one to one line indicates where data points should fall if there were no significant differences between labs and counting methods. Differences in the various methods were evaluated using the Wilcoxon Matched-Pairs Signed-Ranks Test on untransformed abundance values (Appendix B- Comparison of Versar Hensen-Stempel counts vs. ODU corrected CVS counts, Appendix C- Comparisons of Versar Hensen-Stempel counts vs. ODU Hensen-Stempel counts, Appendix D- Comparison of Versar Hensen-Stempel counts vs. ODU corrected CVS counts).

Table 1. Commonly computed mesozooplankton metrics used for method comparison.

ACARTIA_ABUNDANCE	BALANIDAE_ABUNDANCE
BLUE_CRAB_ABUNDANCE	BOSMINA_ABUNDANCE
CALANOIDA_ABUNDANCE	CLADOCERA_ABUNDANCE
COPEPODA_ABUNDANCE	CYCLOPOIDA_ABUNDANCE
EURYTEMORA_ABUNDANCE	HARPACTICOIDA_ABUNDANCE
MARGALEFS_INDEX	PREDATOR_ABUNDANCE
SIMPSON'S DIVERSITY INDEX	SHANNON-WEINER DIVERSITY INDEX
TAXA_RICHNESS	TOTAL_ABUNDANCE

Through all comparisons Blue Crab abundance, *Bosmina* abundance, *Eurytemora* abundance, and Harpacticoida abundance show a lot of scatter due to low densities of organism. This may be a function of these organisms not being present in the target season and/or salinity regimes rather than method or between laboratory biases.

MZ101C/MZ102_C Comparisons

The comparisons are based 28 samples and data denoted as blue dots in all graphs in Appendix A with accompanying statistics in Appendix B. In zooplankton groups which are prevalent in summer (July- September) mesohaline and polyhaline waters (*Acartia* abundance, *Balanidae* abundance, *Calanoida* abundance, *Cladocera* abundance, *Copepoda* abundance, Predator abundance, Total Abundance) when density dropped below 1000 organisms per meter cubed Versar was finding higher abundances. Above the 1000 organism per meter cubed threshold densities for all MZ102_C counts between the labs converged. There was clear bias in *Cyclopoida* abundance, Versar counts were generally higher than ODU (Wilcoxon Signed Rank Test, $S=113$, $P=<.0001$). Over the entire version 1 CVS correction factors developed for the polyhaline ZIBI appear to be effective in equilibrating abundance measurement to HS enumerated values in summer mesohaline and polyhaline region.

Examination of the four measures of species diversity (Margalef's index, Simpson's diversity index, Shannon Weiner index, and taxa richness) provided a mixed picture. Simple taxa richness (taxa count) and Margalef's index both graphically and statistically shows a clear bias toward HS method consistently identifying more taxa than CVS method counts (MZ101C/MZ102_C and MZ103/MZ102_C comparisons). This trend is particularly disturbing since one of the purported strengths of the CVS method was it allowed for rare and common abundant species to be enumerated with equal precision. These analyses also showed that Simpson's diversity index and Shannon-Weiner index do not have the same bias. This was not unexpected because both Simpson's and Shannon Weiner indexes are based on species proportion as part of total abundance, which itself did not show any method biases (ICES, 2000).

MZ101C/MZ103 Comparisons

MZ101C/MZ103 comparisons were also based 28 samples, are denoted as green dots in all graphs in Appendix A with accompanying statistics in Appendix C. Overall mesozooplankton data enumerated by Old Dominion University using Hensen-Stempel methodology is reasonably compatible with its Versar counter part. Just like the MZ101C/MZ102_C data, MZ101C/MZ103 also showed density dropped in common groups below 1000 organisms per meter cubed with the same Versar bias. In regards to species diversity Versar consistently found more taxa per sample than ODU (Wilcoxon Signed Rank Test, $S=173.5$, $P= <.0001$). However it may be possible to adjust this gap by collapsing taxa to Genus or other larger group before calculating diversity metrics.

MZ103/MZ102_C Comparisons

MZ103/MZ102_C comparisons were based on 55 samples, denoted as red dots in all graphs in Appendix A and statistics in Appendix D. In these comparisons the corrected CVS data is plotted and being assessed against the HS data used to derive the version 1 correction factors. There were no

observed biases at the 1000 organism per meter cubed threshold found as in the MZ101C/MZ102_C and MZ101C/MZ103 comparisons. There was clear bias in Cyclopoida abundance, at densities fewer than 10 per meter cubed the CVS counts seem to missing or severely under counting this taxa group. Over all CVS correction factors developed for the polyhaline ZIBI appear to be effective in equilibrating abundance measurement to HS enumerated values in summer mesohaline and polyhaline region

Refinement of CVS correction Factors

One short coming of the Version 1 CVS correction factors was that genus specific correction factors could not be calculated for all major groups due a low number of occurrences in the original 189 ODU Hensen Stempel recount samples. The addition of the 72 Versar recounts samples to the pool it is now possible to refine existing correction factors and calculate taxa specific correction factors for *Evdne* sp., *Labidocera* sp., *Leptodora* sp., *Podon* sp, and *Penilia* sp.. Previously these taxa had been lumped into group correction factors. Version 2 correction factors have been calculated using the same procedure used previously. First all "exclusion" taxa were removed from the data set (Table 2). Exclusion taxa are those taxa appearing in the data set not considered to be true mesozooplankton or plankton not well sampled by bongo net protocols. All taxa identified to species were group to genus and life stage designations for most species were removed. CVS and HS data were then matched by station, date and taxa. Correction factors were then estimated for each taxa by calculating the difference between the Log10(Hensen Stempel Count) - Log (CVS Count), computing the average of all differences for each taxa and then take the antilog of difference the resulting value is the correction factor. The resulting correction factors and the original correction factors can be found in Table 3.

$$\text{anti log}(\text{average}(\sum \log(HS_count) - \log(CVS_count)))$$

For taxa groups where sample size was less than 5 in most cases, groups were pooled to calculate order or other higher level taxonomic level conversion factor.

Validation of Zooplankton Indices of Biotic Integrity

Independent validations of the published polyhaline ZIBI (Carpenter et al., 2006) and the mesohaline ZIBI (Sillett et al. 2005) still under development were performed using counts of the archive samples. Of the 72 archives samples counted by Versar with Hensen-Stempel method (MZ102C), 32 were from polyhaline regions and 31 were from mesohaline regions of the bay (Appendix E). Another 9 samples were from areas of known salinity but had no acceptably matching water quality data based on the protocol used in the development of both ZIBI's (Carpenter et al., 2006, Sillett et al., 2005). These 9 samples were not used for validation purposes. Of the 87 archived samples enumerated by ODU with the Hensen-Stempel method (MZ103), 38 samples were of the correct season and salinity zones (11 mesohaline, 27 polyhaline) to be used in the IBI validation. Rotifer data for the IBI calculations were drawn from the separate Virginia and Maryland microzooplankton data sets.

The overall mesohaline ZIBI validated well, correctly identifying all the BAD (degraded) sites and the one GOOD (least-impaired) site, and identifying approximately half (57.9%) of the MIXED sites as impaired. These results validate the draft mesohaline ZIBI as a potential management tool. Discrimination efficiencies of most of the component metrics also performed well. However, the balanidae larvae discrimination efficiency was low (<<50%). Barnacle larvae discrimination efficiency in the calibration data set used to develop the mesohaline ZIBI was only 63.2%. The combined calibration and validation results put into question the usefulness of balanidae larvae as a metric sensitive to habitat conditions as they were defined for purposes of building an IBI. The rotifer discrimination efficiency was borderline (45.5%) in BAD habitats in the validation data set; it was high (80%) in GOOD habitats and relatively low (57.6%) in BAD habitats in the calibration data set. These results suggest that, barring any taxonomic identification differences between the states, rotifer abundance may be a robust indicator of least-impaired (GOOD) conditions but not of degraded (BAD) conditions.

The validation results for the polyhaline ZIBI suggest the original metric scoring thresholds should be recalculated. The polyhaline ZIBI scoring thresholds were developed from a combination of MZ102 data adjusted with the original correction factors (1993 – 1997) and MZ103 data (2000 – 2002). The addition of the Versar Hensen-Stempel counts of archived polyhaline samples (MZ101C) to the ODU Hensen-Stempel counts of archived samples (MZ103) produced version 2 of the correction factors (Table 2), with differences ranging from -146% to +38%. These new correction factors will further adjust the original MZ102 data values in the calibration data set. They can be expected to change the original metric scoring thresholds of the polyhaline ZIBI. Despite this, the original polyhaline ZIBI thresholds correctly classified 72.7% of the BAD sites in the validation data set, as compared to 93.6% in the original, calibration data set. Discrimination efficiencies for the copepod (sum of all copepod taxa), rotifer, and total mesozooplankton abundance metrics were poor, however.

The current ZIBI validation efforts suggest that more counts of archived samples from reference conditions are required for a thorough evaluation of indices. The original development process for the

polyhaline ZIBI should be repeated and new metric scoring thresholds calculated. The new calibration data set should include the MZ102 data adjusted with the latest correction factors and all the Versar and ODU counts of archived samples be used in the development and validation of the new scoring thresholds.

Classification efficiencies for the mesohaline ZIBI and discrimination efficiencies of the individual ZIBI metrics. The numbers and percentages of samples whose metrics or IBI score correctly identify BAD (impaired) and GOOD (least-impaired) habitat conditions are shown. The numbers and percentages of MIXED habitat conditions identified by the IBI as impaired (~50% expected) are also shown.
