The ICPRB, through its Section for Cooperative Water Supply Operations on the Potomac (CO-OP), coordinates water supply operations during times of drought and recommends releases of stored water. These operations ensure adequate water supplies for the major Washington metropolitan area water users and for environmental flow levels. The water supply outlooks are published by CO-OP on a monthly basis between April and October. They are meant to provide an update on the possibility of low-flow conditions in the Potomac basin.

Summary/Conclusions:

There is a below normal probability of releases from the Washington metropolitan area’s back-up water supply reservoirs for the 2016 summer and fall seasons. Generally, the use of Jennings Randolph and Little Seneca reservoirs is triggered by low flows brought about by a combination of low summer precipitation and low groundwater levels. The MARFC’s Water Resource Outlook for the southern portion of the Middle Atlantic reports that precipitation in the month of March has been below normal, with a basin averaged precipitation 1.7 inches below normal. Precipitation is expected to be above normal in April. At present, there is sufficient flow in the Potomac River to meet the Washington metropolitan area’s water demands without augmentation from upstream reservoirs. In the event that low-flow conditions do develop, the Washington metropolitan area is well-protected from a water supply shortage because of carefully designed drought-contingency plans.

ICPRB’s Low Flow Outlook:

There is a 4 to 8 percent conditional probability that natural Potomac flow will drop below 600- to 700-million gallons per day (MGD) at Little Falls through December 31 of this year; at these flow levels, water supply releases from Jennings Randolph and Little Seneca reservoirs may occur. Releases occur when predicted flow is less than demand plus a required flow-by. Drinking water demand ranges from 400 to 700 MGD during the summer months and the minimum flow-by at Little Falls is 100 MGD. Note that natural flow is defined as observed flow at the Little Falls gage plus total Washington metropolitan Potomac withdrawals, with an adjustment made to remove the effect of North Branch reservoir releases on stream flow.

The conditional probability is estimated by analyzing the historical stream flow records and giving consideration to recent stream flow values, precipitation totals for the prior 12 months, current groundwater levels, and the current Palmer Drought Index. Past years in which watershed conditions most closely resemble current conditions are weighted more heavily in the determination of conditional probability. The historical, or unconditional, probability is based on an analysis of the historical record without weighing for current conditions. The conditional probability of 4 to 8 percent compares to a historical probability of 8 to 15 percent and is considered the more reliable indicator.

Past Precipitation:

Data from the National Weather Service's Middle Atlantic River Forecast Center (MARFC) shows that the Potomac basin upstream of Washington, D.C. has received a precipitation total of 1.7 inches for the month of March, which is 1.7 inches below normal. The map below shows that March precipitation has been 10 to more than 75 percent below normal across the Potomac basin. But thanks to sustained above normal precipitation in December, January and February, the 12-month cumulative basin precipitation is 1.8 above normal (see graph).

Precipitation and Drought Outlook for April, May and June 2016:

MARFC's Water Resource Outlook for the southern portion of the Middle Atlantic for the next couple of weeks calls for near to above normal rainfall, and mostly below normal temperature.

The NWS Climate Prediction Center’s 30 day outlook for April calls for normal rainfall and normal temperatures. The 90 day outlook for April through June calls for normal precipitation and above normal temperature.

As of March 31, the Climate Prediction Center’s U.S. Seasonal Drought Outlook indicates that drought development is not likely for the Potomac basin.

**Groundwater – Current Conditions:**

MARFC’s Water Resource Outlook for the southern portion of the Middle Atlantic reports that groundwater levels are generally near or below normal. The groundwater map below, created by the U.S. Geological Survey (USGS), Pennsylvania Water Science Center, shows that current water levels in monitoring wells in the Potomac basin range from “Below Normal” to “Normal”, with most falling in the “Normal” category. In this map, the USGS defines “Normal” as between the 25th and 75th percentiles, and “Below Normal” as between the 10th and 24th percentile.

**Potomac River Flow:**

The estimated adjusted Potomac flow at Little Falls on April 1 was 6.51 billion gallons per day (BGD). For this day of the year, this value was above the historical 10\(^{th}\) percentile value of 5.69 BGD and below the 50\(^{th}\) percentile value of 11.1 BGD. Adjusted flow, shown in the figure below, is the flow that would occur in the absence of major Washington metropolitan area withdrawals, but includes releases from upstream reservoirs. Adjusted flow averaged 14.4 BGD for the first three months of the year and 9.65 BGD in March.

**Environmental Flow-by:**

Average observed Potomac flow at Little Falls in March was well above the minimum flow recommendation of 100 MGD.

---

*Little Falls flow statistics are based on 1930 through 2014 USGS published gage flow, “USGS 01646502 POTOMAC RIVER (ADJUSTED) NEAR WASH, DC”. To create this flow record, the USGS has added historical water supply withdrawals from the Potomac as reported by FW, WSSC, the Aqueduct, and Rockville to the Little Falls gage flow record.*

Information provided by the USGS, the Middle Atlantic River Forecast Center, and the National Weather Service.
**Drought Status:**

The Metropolitan Washington Council of Government's Drought Awareness Response Plan status is "Normal".

**Drought Monitor and Soil Moisture:**

The NOAA Climate Prediction Center's U.S. Drought Monitor map (see first figure below) indicates abnormally dry conditions for a small portion of the Potomac basin. The Palmer Drought Severity Index by Division map (see second figure below) indicates near normal conditions in the Potomac basin.
