The ICPRB, through its Section for Cooperative Water Supply Operations on the Potomac (CO-OP), coordinates water supply operations during times of drought and recommends releases of stored water. These operations ensure adequate water supplies for Washington metropolitan area water users and for environmental flow levels. The water supply outlooks are published by CO-OP on a monthly basis between April and October. They are meant to provide an update on the possibility of low-flow conditions in the Potomac basin.

Summary/Conclusions:

There is an above normal probability of releases from the Washington metropolitan area’s back-up water supply reservoirs for the 2022 summer and fall seasons. The use of Jennings Randolph and Little Seneca reservoirs is generally triggered by low flows brought about by a combination of low summer precipitation and low groundwater levels. Average precipitation in the Potomac Basin in April was 0.8 inches below normal. The 12-month cumulative basin precipitation is 5.6 inches below normal as of April 30. But recent heavy rainfalls have reduced the deficit recorded over the past months. Streamflow is currently above normal, and groundwater levels remain normal for most of the monitoring wells in Maryland. The Middle Atlantic River Forecast Center’s (MARFC) outlook indicators for water resources and supplies for the Potomac Basin are good. At present, there is sufficient flow in the Potomac River to meet the Washington metropolitan area’s water demands without releases from upstream reservoirs. If low-flow conditions do develop, the Washington metropolitan area is well-protected from a water supply shortage owing to carefully designed drought-contingency plans.

ICPRB’s Low Flow Outlook:

There is a 12 to 21 percent conditional probability that natural Potomac flow will drop below 600 to 700 million gallons per day (MGD) at Little Falls through December 31 of this year; at these flow levels, water supply releases from Jennings Randolph and Little Seneca reservoirs may occur. Releases occur when predicted flow is less than demand plus a required environmental flow-by. Drinking water demand ranges from 400 to 700 MGD during the summer months and the minimum flow-by at Little Falls is 100 MGD. Note that natural flow is defined as observed flow at the Little Falls gage plus total Washington metropolitan Potomac withdrawals, with an adjustment made to remove the effect of North Branch reservoir releases on stream flow.

The conditional probability is estimated by analyzing the historical stream flow records and considering recent stream flow values, precipitation totals for the prior 12 months, current groundwater levels, and the current Palmer Drought Index. Past years in which watershed conditions most closely resemble current conditions are weighted more heavily in the determination of conditional probability. The historical, or unconditional, probability is based on an analysis of the historical record without weighing for current conditions. The 12 to 21 percent conditional probability compares to the 8 to 15 percent historical probability and is considered the more reliable indicator.

Past Precipitation:

Data from the National Weather Service’s Middle Atlantic River Forecast Center (MARFC) shows that the Potomac basin upstream of Washington, D.C. has received 2.6 inches of precipitation for the month of April, which is 0.8 inches below normal. The 12-month cumulative basin precipitation is 5.6 inches below normal as of April 30 (see graph). Recent heavy rainfalls in May have reduced the deficit observed in the past months.

Precipitation and Drought Outlook for May, June, and July 2022:

The Middle Atlantic River Forecast Center’s (MARFC) outlook for water resources and supplies is fair.

The National Weather Service Climate Prediction Center’s one-month outlook for April calls for above normal temperatures and normal precipitation in the Potomac Basin. The 90-day outlook for May through July calls for above normal temperatures and above normal precipitation.

As of April 30, 2022, the Climate Prediction Center’s U.S. Seasonal Drought Outlook reports no drought development in the Potomac basin.
**Groundwater – Current Conditions:**

The groundwater map below, developed by the U.S. Geological Survey (USGS), Pennsylvania Water Science Center, shows that current water levels in most monitoring wells in the Potomac basin are in the “Normal” range. Wells with a gray dot inside the symbol identify Water Supply Outlook wells. In this map, the USGS defines “Normal” as between the 25th and 75th percentiles, and “Below Normal” as between the 10th and 24th percentile. “Much Below Normal” is defined as below the 10th percentile.

**Reservoir Storage – Current Conditions:**

No water supply releases from the CO-OP shared system have been made this year. The whitewater releases which were scheduled for Jennings Randolph Lake for May 7 and 8, 2022, are cancelled due to forecasted rainfall and anticipated high inflows. The forecasted rainfall is anticipated to result in the need for variable increased releases from Jennings Randolph Lake over the next few days.
Reservoir storage as of May 6, 2022

⁴ 1998 revised stage-storage curve provided by Bill Haines, US Army Corps of Engineers, Baltimore District.

**Potomac River Flow:**

The estimated adjusted Potomac flow at Little Falls on May 1 was 6.0 billion gallons per day (BGD). For this day of the year, this value was below the 50th percentile flow value of 8.0 BGD and above the 10th percentile flow value of 4.2 BGD. Adjusted flow, shown in the figure below, is the flow that would occur in the absence of major Washington metropolitan area withdrawals, but includes releases from upstream reservoirs. Adjusted flow averaged 8.1 BGD for the past four months and 11 BGD in April. Streamflow is currently above normal.

**Environmental Flow-by:**

Average observed Potomac flow at Little Falls in April was well above the minimum recommendation of 100 MGD.

![Graph showing adjusted flows of Potomac River with Little Falls flow statistics based on 1930 through 2020 USGS published gage flow, “USGS 01646502 POTOMAC RIVER (ADJUSTED) NEAR WASH, DC”](image)

*Little Falls flow statistics are based on 1930 through 2020 USGS published gage flow, “USGS 01646502 POTOMAC RIVER (ADJUSTED) NEAR WASH, DC”. To create this flow record, the USGS has added historical water supply withdrawals from the Potomac as reported by U.S. Army Corps of Engineers, Washington Suburban Sanitary Commission, Fairfax County Water Authority, city of Rockville, and Loudoun Water to the Little Falls gage flow record.*
**Drought Status:**

Drought status is normal in Maryland’s central region, most of Virginia and in Pennsylvania. The Western region in Maryland and the Roanoke and Eastern Shore region in Virginia are in drought watch. The current drought stage, as defined in the Metropolitan Washington Council of Governments (MWCOG)’s water supply and drought response awareness plan, is normal.

**Drought Monitor and Soil Moisture:**

The NOAA Climate Prediction Center’s U.S. Drought Monitor map (see first figure below) indicates the presence of abnormally dry (D0) conditions in the Potomac basin. The Palmer Drought Severity Index by Division map (see second figure on next page) indicates no drought conditions in most of the basin.
Drought Severity Index by Division
Weekly Value for Period Ending May 01, 2021
Long Term Palmer

Drought Severity Index (Palmer)

Defects prolonged periods of abnormally dry or
wetness improves slowly; changes little from week to week;
and reflects long-term moisture surplus, deficit, and deep
percolation as well as evaporative transport.

Uses... applicable in measuring disruptive effects of prolonged dryness
on wetness on water sensitive economies, designing disaster areas of drought
or wetness, and reflecting the general long-term status of water supplies
in aquifers, reservoirs and streams.

Limitations... is not generally indicative of short-term (few weeks) status
of drought or wetness such as frequently affects crops and field operations
(this is indicated by the crop moisture index).

-4.0 or less (Extreme Drought)
-3.0 to -3.9 (Severe Drought)
-2.0 to -2.9 (Moderate Drought)
-1.9 to +1.9 (Near Normal)
+2.0 to +2.9 (Unusual Moist Spell)
+3.0 to +3.9 (Very Moist Spell)
+4.0 and above (Extremely Moist)
